STUDIES RELATED TO WILDERNESS

Bureau of Land Management Wilderness Study Areas

The Federal Land Policy and Management Act (Public Law 94-579, October 21, 1976) requires the U.S. Geological Survey and the U.S. Bureau of Mines to conduct mineral surveys on certain areas to determine their mineral values, if any. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of a geochemical survey of the Continental Divide and Horse Mountain Wilderness Study Areas, Catron County, New Mexico.

INTRODUCTION

In November 1984, the U.S. Geological Survey conducted reconnaissance geochemical surveys of the Continental Divide and Horse Mountain Wilderness Study Areas, Catron County, New Mexico.

The Continental Divide Wilderness Study Area comprises about 59 mi^2 (152 km^2) (37,600 acres) and Horse Mountain Wilderness Study Area comprises about 7 mi^2 (18 km^2) (4,400 acres) in the southeast corner of Catron County, New Mexico. Continental Divide WSA lies about 35 miles southwest of Datil, New Mexico, and is between New Mexico State Highways 12 to the north and 78 to the south (fig. 1). Along the north, west, and south boundaries there are some dirt roads which provide access to this study area. Horse Mountain WSA lies about 20 miles southwest of Datil, New Mexico, and is just to the northwest of New Mexico State Highway 12 (fig. 1). Access to the flanks of this study area is by dirt roads.

In the Continental Divide WSA elevations range from about 7,000 ft where Cottonwood Canyon crosses the western boundary to 9,220 ft at the top of Pelona Mountain in the west central part of the area. The eastern and southern parts of the area are relatively flat plains covered with sage brush. The west central and northwest parts are hilly with pinyon pine and cedar trees at the highest elevations and cottonwood trees along small streams.

Horse Mountain WSA consists of an isolated mountain mass rising from a plain of about 7,000 ft to 9,550 ft at the top of Horse Mountain. Most of the area is covered with pinyon pine and desert cedar with cottonwood trees in the stream beds and sage brush on the lower flanks of the mountain.

The two study areas are located within the Datil-Mogollon Volcanic plateau. This area is transitional between the Basin and Range Province and the Colorado Plateau. The Plains of San Agustin, which separate the two study areas, have many features typical of a classic block-faulted Basin and Range valley. The major geologic features are Horse Mountain in the northern study area and Pelona Mountain in the southern study area. Horse Mountain is a composite volcanic dome of dacitic to rhyolitic composition. The rocks of this volcano are mainly lava flows and flow breccia which presently cover an area about 4 mi in diameter.

Pelona Mountain is a shield volcano of andesitic composition consisting mainly of lava flows about 6,500 ft thick. The lava flows overlie rhyolitic ash-flow tuffs and lava flows. Further discussion of the geology of the areas is given in Ratte and others (1988) and Stearns (1962).

The terrain has a moderate slope ascending from the nearly flat Plains of San Agustin to Horse Mountain in the north and Pelona Mountains to the south. The Plains of San Agustin are nearly bare but higher up the slopes there is ponderosa pine, pinyon pine, junipers, and oaks. The streams are intermittent and the climate is semiarid.

METHODS OF STUDY

Sample Media

Analyses of the stream-sediment samples represent the chemistry of the rock material eroded from the drainage basin upstream from each sample site. Such information is useful in identifying those basins which contain concentrations of elements that may be related to mineral deposits. Heavy-mineral-concentrate samples provide information about the chemistry of certain minerals in rock material eroded from the drainage basin upstream from each sample site. The selective concentration of minerals, many of which may be ore related, permits determination of some elements that are not easily detected in stream-sediment samples.

Analyses of unaltered or unmineralized rock samples provide background geochemical data for individual rock units. On the other hand, analyses of altered or mineralized rocks, where present, may provide useful geochemical information about the major- and trace-element assemblages associated with a mineralizing system.

Sample Collection

Heavy-mineral-concentrate samples were collected at 61 sites in the Continental Divide WSA (fig. 2) and 8 sites in the Horse Mountain WSA (fig. 3). Stream-sediment samples were only collected in the Continental Divide WSA, of which there were 59. Fourteen rock samples were collected in the Continental Divide WSA and three rocks were collected in the Horse Mountain WSA. Average sampling density in the Continental Divide WSA was about one sample site per 1 mi² for the stream sediments and heavy-mineral concentrates, and about one sample site per 4 mi² for the rocks. Average sampling density in the Horse Mountain WSA was about one sample site per 1 mi² for the heavy-mineral concentrates and 2 mi² for the rocks. The area of the drainage basins sampled ranged from 0.5 mi² to 2 mi².

Stream-sediment samples

The stream-sediment samples consisted of active alluvium collected primarily from first-order (unbranched) and second-order (below the junction of two first-order) streams as shown on USGS topographic maps. Each sample was composited from several localities within an area that may extend as much as 50 ft from the site plotted on the map.

Heavy-mineral-concentrate samples

Heavy-mineral-concentrate samples were collected from the same active alluvium as the stream-sediment samples. Each bulk sample was screened with a 2.0-mm (10-mesh) screen to remove the coarse material. The less than 2.0-mm fraction was panned until most of the quartz, feldspar, organic material, and clay-sized material were removed.

Rock samples

Rock samples were collected from outcrops or exposures in the vicinity of the plotted site location. Samples were collected from unaltered and altered and mineralized rocks. Descriptions of rock samples are in table 6.

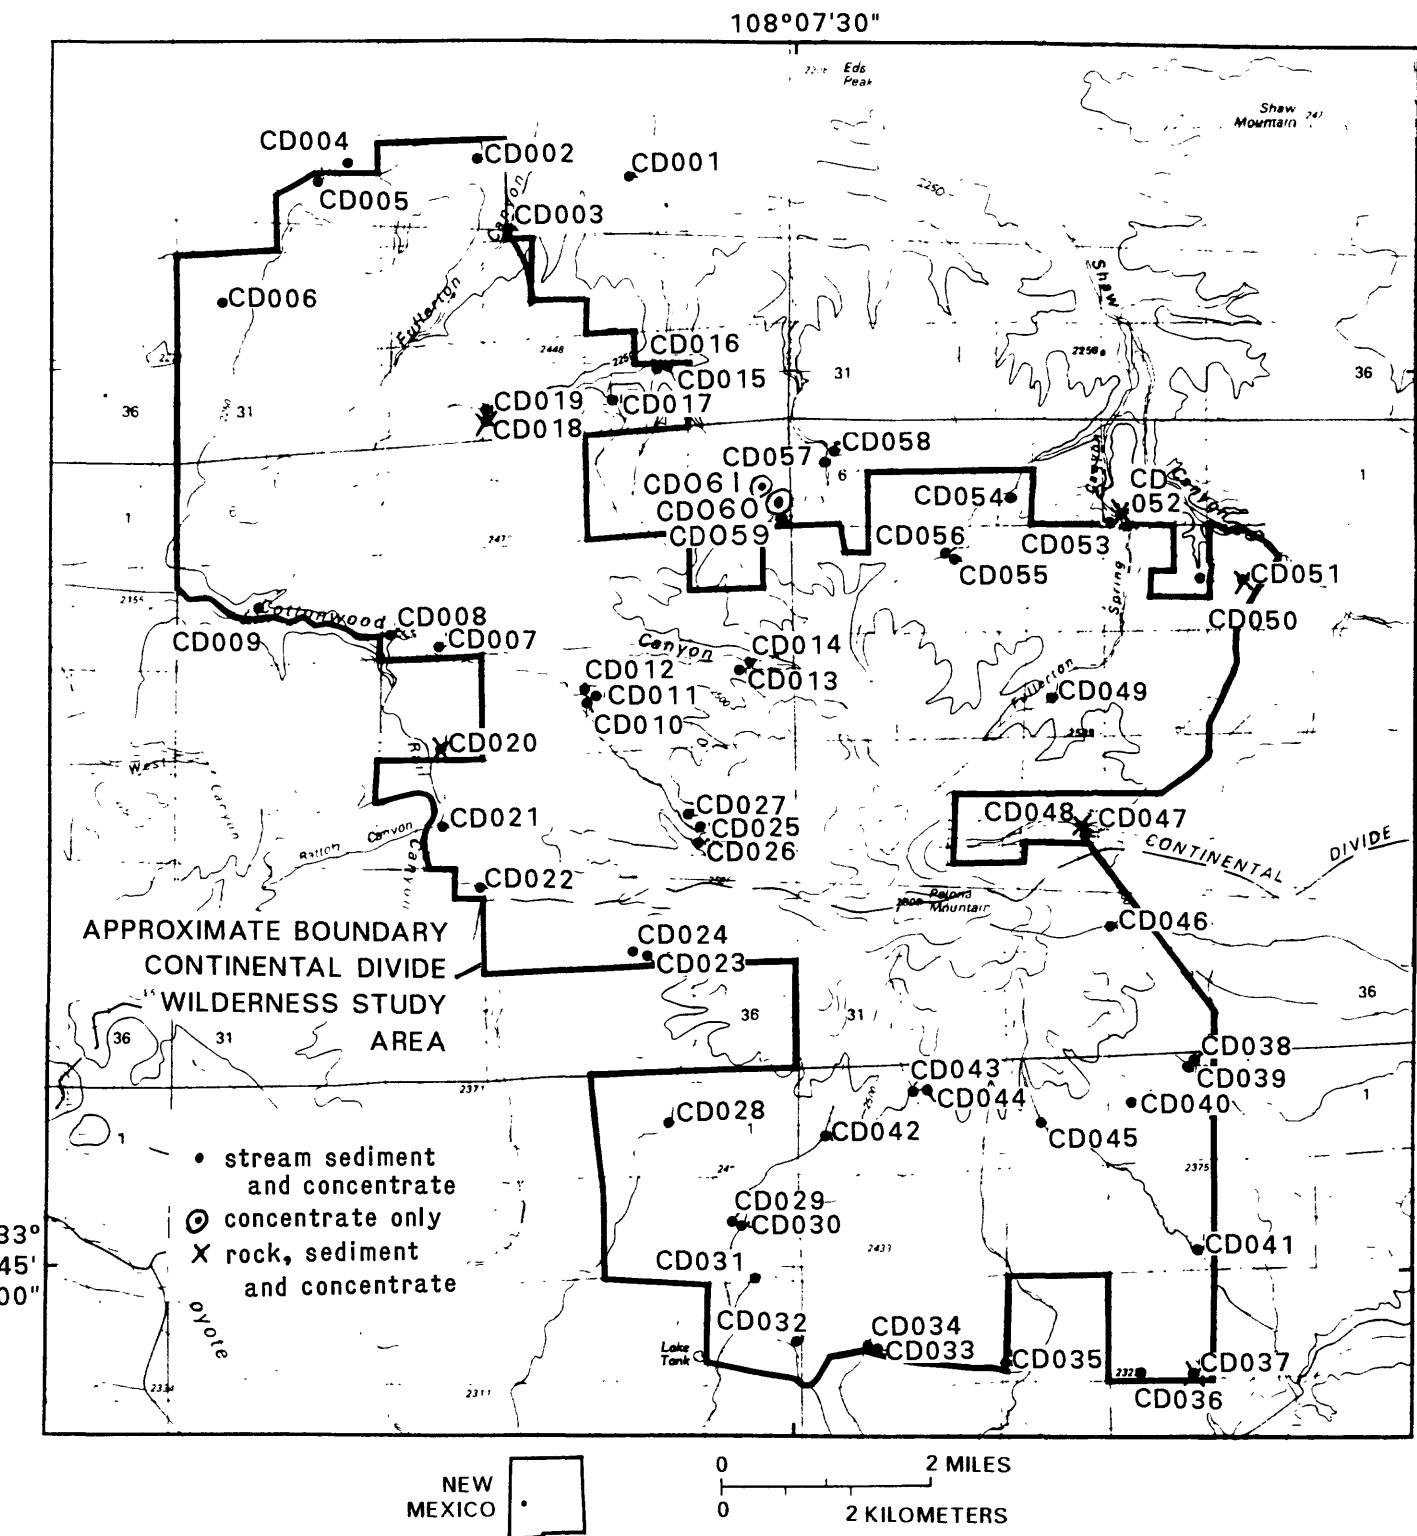

Figure 2. Localities of stream-sediment, heavy-mineral-concentrate, and rock samples from the Continental Divide (NM-020-044) Wilderness Study Area, Catron County, New Mexico.

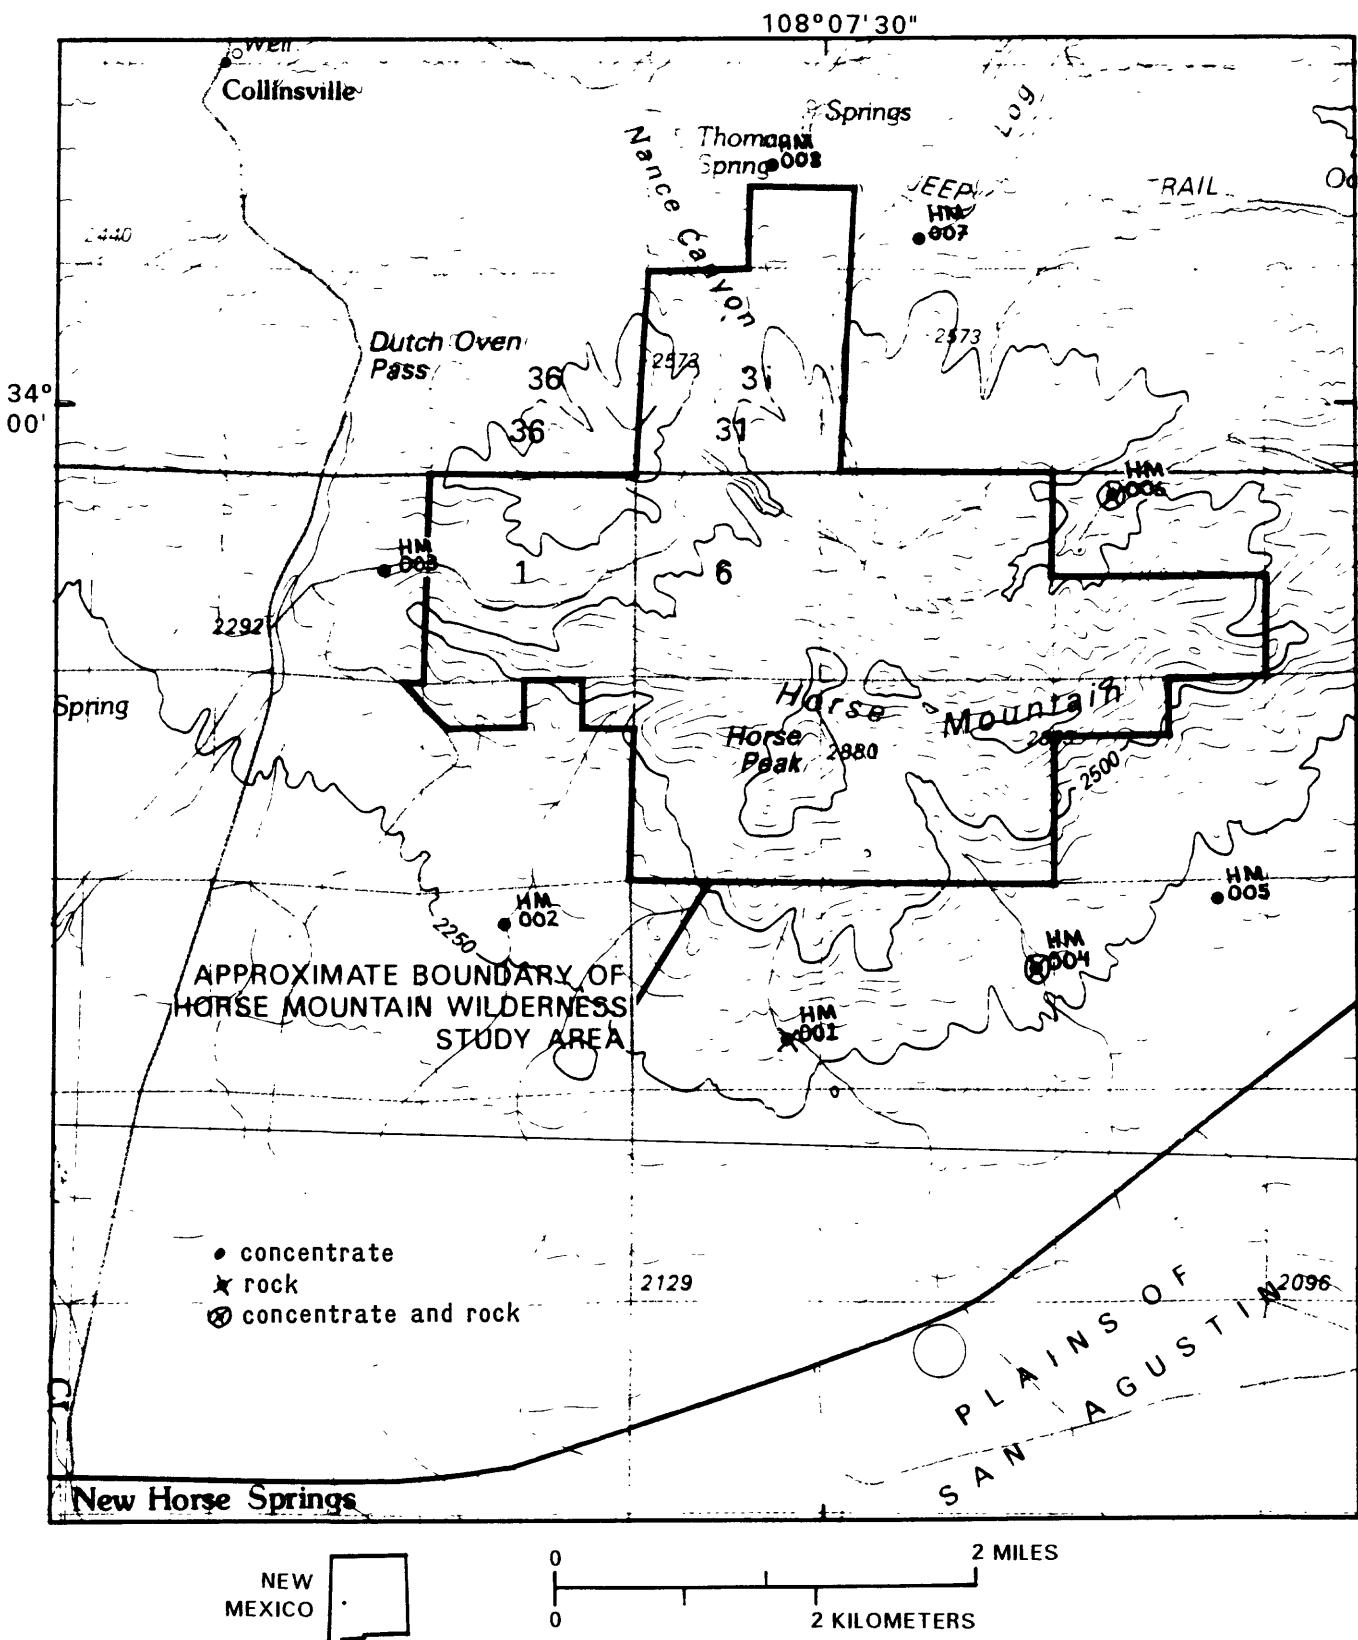

Figure 3. Localities of heavy-mineral-concentrate and rock samples from the Horse Mountain (NM-020-043) Wilderness Study Area, Catron County, New Mexico.

Sample Preparation

The stream-sediment samples were air dried, then sieved using 80-mesh (0.17-mm) stainless-steel sieves. The portion of the sediment passing through the sieve was saved for analysis.

After air drying, bromoform (specific gravity 2.8) was used to remove the remaining quartz and feldspar from the heavy-mineral-concentrate samples that had been panned in the field. The resultant heavy-mineral sample was separated into three fractions using a large electromagnet (in this case a modified Frantz Isodynamic Separator). The most magnetic material, primarily magnetite, was not analyzed. The second fraction, largely ferromagnesian silicates and iron oxides, was analyzed. The third fraction (the least magnetic material which may include the nonmagnetic ore minerals, zircon, sphene, etc.) was split using a Jones splitter. One split was hand ground for spectrographic analysis; the other split was saved for mineralogical analysis. There was an insufficient amount of the nonmagnetic fraction for 44 samples from the Continental Divide WSA, therefore, the second fraction or the "slightly magnetic" fraction was also split, hand ground, and analyzed. These magnetic separates are the same separates that would be produced by using a Frantz Isodynamic Separator set at a slope of 15° and a tilt of 10° with a current of 0.1 ampere to remove the magnetite and ilmenite, and a current of 1.0 ampere to split the remainder of the sample into paramagnetic and nonmagnetic fractions.

Rock samples were crushed and then pulverized to minus 0.15 mm with ceramic plates.

Sample Analysis

Spectrographic method

The stream-sediment, heavy-mineral-concentrate, and rock samples were analyzed for 31 elements using semiquantitative, direct-current arc emission spectrographic methods. The analyses for heavy-mineral-concentrate samples were performed by analysts in the Branch of Exploration Geochemistry using the method of Grimes and Marranzino (1968); analyses for stream-sediment and rock samples were performed by analysts in the Branch of Analytical Chemistry using the method of Myers and others (1961). The elements analyzed and their lower limits of determination are listed in table 1. For arsenic (As), gold (Au), cadmium (Cd), lanthanum (La), and thorium (Th), the lower limits of determination of the two analytical methods varies. The values in the parentheses are the limits of determination for Myers and others (1961). Spectrographic results were obtained by visual comparison of spectra derived from the sample against spectra obtained from standards made from pure oxides and carbonates. Standard concentrations are geometrically spaced over any given order of magnitude of concentration as follows: 100, 50, 20, 10, and so forth. Samples whose concentrations are estimated to fall between those values are assigned values of 70, 30, 15, and so forth. The precision of the analytical method is approximately plus or minus two reporting interval at the 83 percent confidence level and plus or minus one reporting intervals at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements (iron, magnesium, calcium, and titanium) are given in weight percent; all others are given in parts per million (micrograms/gram). Analytical data for samples from the Continental Divide and Horse Mountain Wilderness Study Areas are listed in tables 3-5.

Chemical methods

Rock and stream-sediment samples from these study areas were also analyzed for arsenic, antimony, zinc, bismuth, and cadmium using an inductively coupled plasma-atomic emission spectrographic method (Crock and others, 1987). See table 2 for a more detailed summary of these analyses.

Analytical results for stream-sediment, heavy-mineral-concentrate, and rock samples are listed in tables 3, 4, and 5, respectively.

DATA STORAGE SYSTEM

Upon completion of all analytical work, the analytical results were entered into either the Branch of Geochemistry data base called Rock Analysis Storage System (RASS) or PLUTO. These data bases contain both descriptive geological information and analytical data. Any or all of this information may be retrieved and converted to a binary form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1977).

DESCRIPTION OF DATA TABLES

Tables 3-5 list the results of analyses for the samples of stream sediment, heavy-mineral concentrate, and rock, respectively. For the five tables, the data are arranged so that column 1 contains the USGS-assigned sample numbers. These numbers correspond to the numbers shown on the site location maps (figs. 2 and 3). Columns in which the element headings show the letter "s" below the element symbol are emission spectrographic analyses; and "icp" indicates inductively coupled plasma-atomic emission spectroscopy. A letter "N" in the tables indicates that a given element was looked for but not detected at the lower limit of determination shown for that element in table 1. For emission spectrographic analyses, a "less than" symbol (<) entered in the tables in front of the lower limit of determination indicates that an element was observed but was below the lowest reporting value. For ICP analyses, a "less than" symbol (<) entered in the tables in front of the lower limit of determination indicates that an element was below the lowest reporting value. If an element was observed but was above the highest reporting value, a "greater than" symbol (>) was entered in the tables in front of the upper limit of determination. If an element was not looked for in a sample, two dashes (--) are entered in tables 3-5 in place of an analytical value. Because of the formatting used in the computer program that produced tables 3-5, some of the elements listed in these tables (Fe, Mg, Ca, Ti, Ag, and Be) carry one or more nonsignificant digits to the right of the significant digits. The analysts did not determine these elements to the accuracy suggested by the extra zeros.

ACKNOWLEDGMENTS

A number of our colleagues also participated in the collection, preparation, and analyses of these samples: collection, Rick Graff and Allen Phillips; preparation, Robin Sanchez; and analyses, John Bullock, Gordon Day, Olga Erlich, and Mollie Malcolm.
